

a CARD strict hits (4 genes, both strains)

b ARDB hits are below the database threshold

c VFDB category counts

Safety-relevant annotations (delivered provider tables):

- CARD strict: four resistance genes at high identity were detected in BOTH strains (a): AAC(6')-II 99.5% (aminoglycoside inactivation), msrC 97.2%, eatAv 96.0% (target protection), efrA 82.6% (efflux). All four are located on the chromosome (not on the shared plasmid or the prophage).
- ARDB: 17 hits at 41–76% identity — all below the database Min_Identity threshold (80%), i.e. not counted as resistance determinants (b).
- VFDB: 128 hits, all flagged "Predicted"; the majority match housekeeping proteins (max identity 99.2%) (c).

Interpretation: the genomes carry several known resistance genes; this should be stated precisely in any safety discussion and differs from a "no resistance genes" claim.
